

KEY to Practice Questions for MA 15300 Test 3 (Sections 2.4, 6.1, 6.2, 3.1, 3.2, and 11.1-11.3)

💡 Open the bookmark panel by selecting the Bookmarks icon  along the side margin to easier navigation.

- 1) The graph of $y = 0.5x^3$ is shown (dashed), along with the graph of $h(x)$ on the set of axes in Figure 1.

Figure 1: Translation of $y = 0.5x^3$ to $y = h(x)$

- Horizontal shift 6 left and vertical shift 4 up.**
Notice B' is $(-6, 4)$ and B is $(0, 0)$.
- $h(x) = 0.5(x + 6)^3 + 4$ (Enter in a grapher to check.)
- Use the graph. Notice A' to see $h(x)$ crosses the x -axis at -8 .
Check with the formula.
If $x = -8$, $h(x) = 0.5(x + 6)^3 + 4$
 $= 0.5(-8 + 6)^3 + 4$
 $= 0.5(-2)^3 + 4$
 $= 0.5(-8) + 4 = 0$.
You can also use the table to check.
- Use the formula. It crosses the y -axis when $x = 0$.
 $h(0) = 0.5(0 + 6)^3 + 4 = 112$. You can also use the table.

- 2) The graph of $y = 0.5x^3$ is shown (dashed), along with the graph of $g(x)$ on the set of axes in Figure 2.

Figure 2: Translation of $y = 0.5x^3$ to $y = g(x)$

- Horizontal shift 5 right and vertical shift 4 down.**
Notice B' is $(5, -4)$ and B is $(0, 0)$.
- $g(x) = 0.5(x - 5)^3 - 4$ (Enter in a grapher to check.)

c) Use the graph. Notice C' to see $g(x)$ crosses the x -axis at 7.

Check with the formula.

$$\begin{aligned} \text{If } x = 7, g(x) &= 0.5(x - 5)^3 - 4 \\ &= 0.5(7 - 5)^3 - 4 \\ &= 0.5(2)^3 - 4 \\ &= 0.5(8) - 4 = 0. \end{aligned}$$

You can also use the table to check.

d) Use the formula. It crosses the y -axis when $x = 0$.

$$g(0) = 0.5(0 - 5)^3 - 4 = -66.5. \text{ You can also use the table.}$$

3) Suppose $y = f(x)$ is given by the graph below.

Figure 3: Graph of $y = f(x)$

Describe each transformation and write a formula for each function in terms of $f(x)$.

a) The graph of $a(x)$ is a horizontal shift of the graph of $y = f(x)$ to the right 6 so $a(x) = f(x - 6)$.

Figure 3a: Graph of $y = f(x)$ and $y = a(x)$.

b) The graph of $y = b(x)$ is a horizontal and vertical reflection of the graph of $y = f(x)$ so $b(x) = -f(-x)$.

$f(-x)$ is a horizontal reflection of $f(x)$.

$-f(-x)$ is a vertical reflection of $f(-x)$.

Figure 3b: Graphs of $y = f(x)$ and $y = f(-x)$ and $y = b(x) = -f(-x)$.

- c) The graph of $y = c(x)$ is a horizontal reflection, followed by a vertical compression by a factor of $\frac{1}{4}$, followed by a vertical shift down 4 units, so $c(x) = \frac{1}{4}f(-x) - 4$.

Figure 3c: Graphs of $y = f(x)$ and $y = f(-x)$ and $y = \frac{1}{4}f(-x)$ and $y = c(x) = \frac{1}{4}f(-x) - 4$.

- 4) Suppose the point $P(3, -2)$ is a point on the graph of $y = f(x)$.

a) Suppose $f(x)$ is **even**:

- Report the coordinates of another point Q , which corresponds to $P(3, -2)$.
Outputs of opposites are the same, so we have $Q(-3, -2)$.
- Plot the point Q on the grid provided.

Figure 4a

b) Suppose $f(x)$ is **odd**:

- Report the coordinates of another point R , which corresponds to $P(3, -2)$.
Outputs of opposites are opposite, so we have $R(-3, 2)$.
- Plot the point R on the grid provided.

Figure 4b

- 5) A ballet dancer jumps in the air. The height, $h(t)$, in feet, of the dancer at time, t in seconds since the start of the jump, is given by $h(t) = -16t^2 + 12t$. No work need be shown. **Do not round off any calculations.**

- To factor $h(t) = -16t^2 + 12t$, remove a greatest common factor of $-4t$: $h(t) = -16t^2 + 12t = -4t(4t - 3)$.
Alternatively: $h(t) = 4t(-4t + 3)$ is also correct. So also is $h(t) = -16t(t - 0.75)$ or $h(t) = 16t(-t + 0.75)$.
- To find the zeros of the function, set each factor equal to 0. Thus the zeros are $t = 0$ and $t = 0.75$.

- c) The vertex of the function can be found on the axis of symmetry. First, plot the zeros. The vertex is midway between them. The x-coordinate of the vertex is $\frac{1}{2} \times 0.75 = 0.375$. Find the y-coordinate of the vertex by substituting $t = 0.375$ in the formula or use a table with $TblStart = 0$ and $\Delta Tbl = 0.375$. We have $y = 2.25$. So the vertex is **(0.375, 2.25)**.

Figure 5c

- d) The equation of the axis of symmetry is $x = 0.375$. The equation $t = 0.375$ is also correct. Reporting simply 0.375 is not correct since the axis of symmetry is an equation of a vertical line.
- e) How much time in seconds is the dancer in the air? **0.75 sec**
- f) What is the maximum height of the jump? **2.25 feet**
- g) When does the maximum height of the jump occur? **0.375 sec**
- h) To write the formula in vertex form, use the fact that the parabola is a translation of $y = at^2$. We are given the formula in standard form $y = at^2 + bt + c = -16t^2 + 12t$ so we know $a = -16$. If we shift $y = -16t^2$ to the right 0.375 and up 2.25, as shown in Figure 5h, we have the translated function $y = -16(t - 0.375)^2 + 2.25$. We can check with a grapher that this produces the same graph and table as $h(t) = -16t^2 + 12t$.

Figure 5h

- 6) Write formulas for the parabolas You may use vertex form, factored form, or standard form, whichever is most efficient. **SHOW ALL WORK.**

a)

Figure 6a: Parabola for part 6a.

You can use factored form since zeros are at 0 and 80 or vertex form since the vertex is at (40, 200).

Method 1: Use factored form: $y = a(x)(x - 80)$

$$\begin{aligned}\text{Substitute a point } x = 40, y = 200 &\Rightarrow y = a(x)(x - 80) \\ 200 &= a(40)(40 - 80) \\ 200 &= -1600a \\ a &= \frac{200}{-1600} \\ a &= -0.125\end{aligned}$$

Divide both sides by -1600 .

The formula in factored form is $y = -0.125(x)(x - 80)$.

Method 2: Alternatively, we could use vertex form: $y = a(x - 40)^2 + 200$

$$\begin{aligned}\text{Substitute a point } x = 80, y = 0 &\Rightarrow y = a(x - 40)^2 + 200 \\ 0 &= a(80 - 40)^2 + 200 \\ 0 &= 1600a + 200 \\ -200 &= 1600a \\ a &= \frac{-200}{1600} \\ a &= -0.125\end{aligned}$$

Divide both sides by 1600 .

The formula in vertex form is $y = -0.125(x - 40)^2 + 200$.

These two formulas are equivalent and either one is correct.

b)

Figure 6b: Parabola for part 6b.

We can only use factored form $y = a(x - 3)(x - 5)$ since we are not given the vertex.

$$\begin{aligned}\text{Substitute a point } x = 10, y = -84 &\Rightarrow y = a(x - 3)(x - 5) \\ -84 &= a(10 - 3)(10 - 5) \\ -84 &= a(7)(5) \\ -84 &= 35a \\ a &= \frac{35}{-84} \\ a &= -2.4\end{aligned}$$

Divide both sides by 35 .

The formula in factored form is $y = -2.4(x - 3)(x - 5)$.

c)

Figure 6c: Parabola for part 6c

We can only use vertex form $y = a(x - 5)^2 + 30$ since there are no zeros.

We can choose a point (0, 60) or (10,60), or others.

$$\begin{aligned} \text{Let's substitute } x = 0, y = 60 \Rightarrow y &= a(x - 5)^2 + 30 \\ 60 &= a(0 - 5)^2 + 30 \\ 60 &= 25a + 30 \\ 30 &= 25a \\ a &= \frac{30}{25} \\ a &= 1.2 \end{aligned}$$

Subtract 30 from both sides.

Divide both sides by 25.

The formula in vertex form is $y = 1.2(x - 5)^2 + 30$.

7) The graph of $y = f(x)$ is shown. It is not a parabola.

Use the graph of $f(x)$ to write $g(x)$ as a transformation of $f(x)$.

Figure 7: Graph of $y = f(x)$ and $y = g(x)$.

The outputs of $g(x)$ are *larger* than those for $f(x)$ so it is a *vertical stretch*. Compare maximum points.

The graph of $g(x)$ is a vertical stretch of the graph of $f(x)$ by a factor of k , where $3k = 12$.

Thus $k = 4$ and $g(x) = 4f(x)$.

8) The graph of $y = f(x)$ is shown. Use the graph of $f(x)$ to write $g(x)$ as a transformation of $f(x)$.

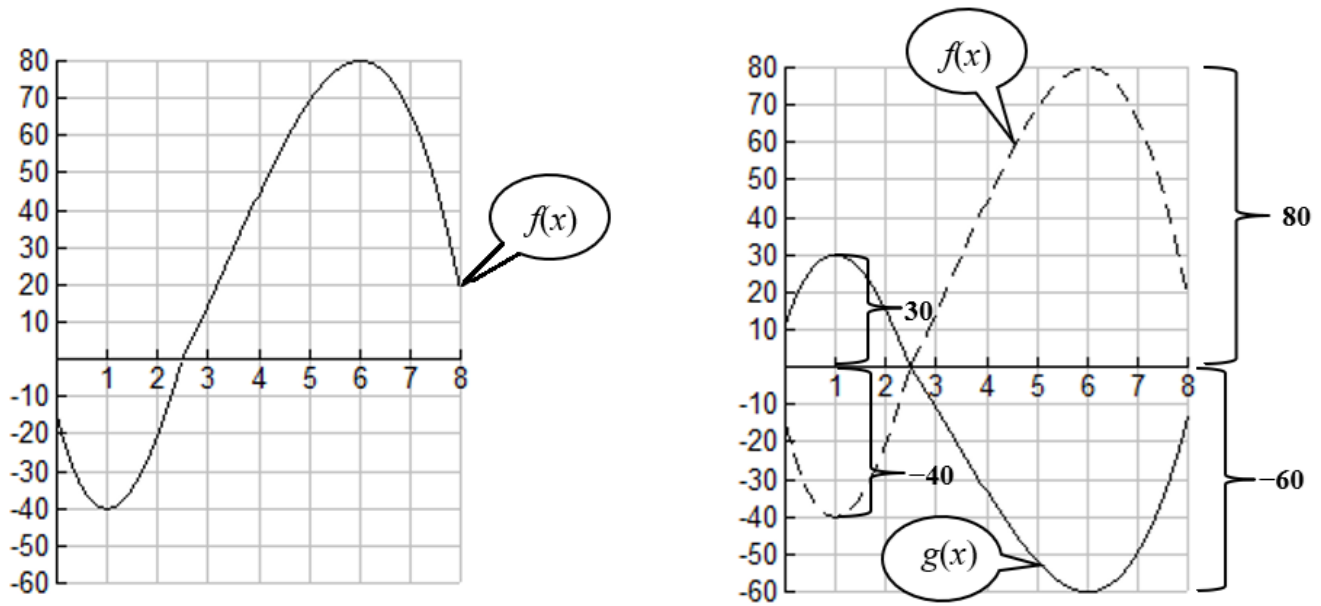

Figure 8b: Graph of $y = f(x)$ and $y = g(x)$.

The outputs of $g(x)$ are *smaller* than those for $f(x)$ so it is a *vertical shrink*. Compare maximum points. The graph of $g(x)$ is a vertical compression of the graph of $f(x)$ by a factor of k , where $80k = -60$. You could also compare minimum points: $-40k = 30$. In either case, $k = -0.75$ and $g(x) = -0.75 f(x)$.

9) The graphs below are power functions of the form $y = kx^p$.

a)

Figure 9a

- i) The leading coefficient, k , is **negative**.
- ii) The power, p , is **odd** (like $\pm 1, \pm 3, \dots$).
- iii) The symmetry of the graph is **odd**.

b)

Figure 9b

- i) The leading coefficient, k , is **positive**.
- ii) The power, p , is **even** (like $\pm 2, \pm 4, \dots$).
- iii) The symmetry of the graph is **even**.

c)

Figure 9c

- i) The leading coefficient, k , is **positive**.
- ii) The power p is **fractional** (like $\pm\frac{1}{2}$, $\pm\frac{1}{3}$, $\pm\frac{1}{4}$, $\pm\frac{1}{5}$, ...).
- iii) The symmetry of the graph is **odd**.

d)

Figure 9d

- i) The leading coefficient, k , is **negative**.
- ii) The power, p , is **odd** (like ± 1 , ± 3 , ...).
- iii) The symmetry of the graph is **odd**.

e)

Figure 9e

- i) The leading coefficient, k , is **negative**.
- ii) The power p is **even** (like ± 2 , ± 4 , ...).
- iii) The symmetry of the graph is **even**.

f)

Figure 9f

- i) The leading coefficient, k , is **positive**.
- ii) The power p is **fractional** (like $\pm\frac{1}{2}$, $\pm\frac{1}{3}$, $\pm\frac{1}{4}$, $\pm\frac{1}{5}$, ...).
- iii) The symmetry of the graph is **neither even nor odd**.

10) Find the formula for the power function $y = kx^p$ given by each table. Show work.

a) Table 10a

x	y
1	2
16	128

Substitute $x = 1, y = 2$ in the formula $y = kx^p$.

$$\begin{aligned} x = 1, y = 2 &\Rightarrow y = kx^p \\ 2 &= k(1)^p \end{aligned}$$

Since $(1)^p = 1$ for any p , we have $2 = k$.

Now substitute $x = 16, y = 128$ in the formula $y = 2x^p$.

$$\begin{aligned} x = 16, y = 128 &\Rightarrow y = 2x^p \\ 128 &= 2(16)^p && \text{Divide both sides by 2.} \\ 64 &= (16)^p && \text{Take common or natural logs of both sides.} \\ \log 64 &= \log(16)^p && \text{Use a property of logs.} \\ \log 64 &= p \log(16) && \text{Divide both sides by } \log 16. \\ p &= \frac{\log 64}{\log 16} = 1.5 \end{aligned}$$

The formula for the power function $y = 2x^{1.5}$. Check with a grapher that your table matches.

b) Table 10b

x	y
81	900
625	1500

Substitute $x = 81, y = 900$ in the formula $y = kx^p$.

$$x = 81, y = 900 \Rightarrow 900 = k \cdot 81^p \quad \text{(Equation 1)}$$

Substitute $x = 625, y = 1500$ in the formula $y = kx^p$.

$$x = 625, y = 1500 \Rightarrow 1500 = k \cdot 625^p \quad \text{(Equation 2)}$$

Divide Equation 1 by Equation 2 to eliminate k .

$$\frac{900}{1500} = \frac{k \cdot 81^p}{k \cdot 625^p}$$

$$\frac{900}{1500} = \frac{81^p}{625^p} \quad \text{Use the cancellation property } \frac{k}{k} = 1.$$

$$\frac{900}{1500} = \left(\frac{81}{625}\right)^p \quad \text{Use a property of exponents.}$$

$$0.6 = \left(\frac{81}{625}\right)^p$$

Solve for p by taking logarithms of both sides (common or natural).

$$\log 0.6 = \log \left(\frac{81}{625}\right)^p$$

$$\log 0.6 = p \log \left(\frac{81}{625} \right)$$

Divide both sides by $\log 16$.

$$p = \frac{\log 0.6}{\log (81/625)} = 0.25$$

Now substitute $x = 81$, $y = 900$ in the formula $y = kx^{0.25}$. (You could also use $x = 625$, $y = 1500$)

$$x = 81, y = 900 \Rightarrow y = kx^{0.25}$$

$$900 = k(81)^{0.25}$$

$$900 = 3k$$

Divide both sides by 3.

$$p = \frac{\log 64}{\log 16} = 1.5$$

The formula for the power function $y = 30x^{0.25}$. Check with a grapher that your table matches.

11) Consider the polynomial $f(x) = 80 + 70x - 30x^3 - 5x^7$.

a) The leading term kx^p is $-5x^7$.

b) The leading coefficient k is -5 .

c) The degree p of $f(x)$ is 7 .

d) The long run behavior of $f(x)$ is “**up down**” or, resembling the graph

that looks like .

12) $g(x) = -20(x-50)^4(x+200)^2 = -20(x^4 + \text{terms of lower degree})(x^2 + \text{terms of lower degree})^2$
 $= -20x^6 + \text{terms of lower degree}$.

a) The leading term kx^p is $-20x^6$.

b) The leading coefficient k is -20 .

c) The degree p of $g(x)$ is 6 .

d) Report the long run behavior of $f(x)$ is “**down down**” or .

13) Use the graph to write each polynomial in factored form.

a) $p(x) = x^3 - 31x + 30 = (x+6)(x-1)(x-5)$ since all of the zeros are single zeros.

Figure 13a

Check that both $x^3 - 31x + 30$ and $(x+6)(x-1)(x-5)$ have the same leading term.

b) $q(x) = x^4 + 3x^3 - 4x = x(x+2)^2(x-1)$ since -2 is a double zero and 0 and 1 are single zeros.

Figure 13b

Check that both $x^4 + 3x^3 - 4x$ and $x(x+2)^2(x-1)$ have the same leading term.

14) Suppose the polynomial f graphed in figure shows its entire long run behavior and has leading term ax^n , that is, $f(x) = ax^n + \text{remaining terms of lower degree}$.

Figure 14

- The degree, n , of the leading term is **even** since both arms go the same way, either both up or both down. In this case both arms are up.
- The leading coefficient, a , is **positive** since both arms are up.
- Report the minimum possible value of n : $n \geq 6$ since there are 6 zeros (and 6 linear factors).

15) Write a possible formula for each polynomial function.

- Consider the polynomial shown. Report long run and short run behavior.

Figure 15a

The long run behavior is "up down" since the arms look like $\uparrow \downarrow$.

The short run behavior:

- -2 is a single zero since, very close to -2 , the graph looks like a line.
- -1 is a double zero, since very close to -1 , the graph bounces.
- 1 is a triple zero, since very close to 1 , the graph looks like a chair.
- 2 is a single zero since, very close to 2 , the graph looks like a line.
- The vertical intercept is $(0, -1)$.

Based on the short run behavior, we have $y = a(x+2)(x+1)^2(x-1)^3(x-2)$, a degree 7 polynomial.

The arms look like  which is consistent with a degree 7 polynomial (arms not doing the same thing.)

Substitute $x = 0, y = -1$ in the formula $y = a(x+2)(x+1)^2(x-1)^3(x-2)$.

$$x = 0, y = -1 \Rightarrow y = a(x+2)(x+1)^2(x-1)^3(x-2)$$

$$-1 = a(0+2)(0+1)^2(0-1)^3(0-2)$$

$$-1 = a(2)(1)^2(-1)(-2)$$

$$-1 = 4a$$

Divide both sides by 4.

$$a = \frac{-1}{4} = -0.25$$

The formula for the polynomial function $y = -0.25(x+2)(x+1)^2(x-1)^3(x-2)$.

Check with a grapher.

b) Consider the polynomial shown. Report long run behavior, zeros, and short run behavior.

Figure 15b

The long run behavior is "up down" since the arms look like .

The short run behavior:

- -3 is a single zero since, very close to -2 , the graph looks like a line.
- -1 is a triple zero, since very close to -1 , the graph looks like a chair.
- 2 is a single zero, since very close to 2 , the graph looks like a line.
- 4 is a double zero since, very close to 4 , the graph bounces.
- The vertical intercept is $(0, 3)$.

Based on the short run behavior, we have $y = a(x+3)(x+1)^3(x-2)(x-4)^2$, a degree 7 polynomial.

The arms look like  which is consistent with a degree 7 polynomial (arms not doing the same thing.)

Substitute $x = 0, y = 3$ in the formula $y = a(x+3)(x+1)^3(x-2)(x-4)^2$.

$$x = 0, y = 3 \Rightarrow y = a(x+3)(x+1)^3(x-2)(x-4)^2$$

$$3 = a(0+3)(0+1)^3(0-2)(0-4)^2$$

$$3 = a(3)(1)^3(-2)(16)$$

$$1 = -32a$$

Divide both sides by 3.

Divide both sides by -32 .

$$a = \frac{1}{-32} = -0.3125$$

The formula for the polynomial function $y = -0.3125(x+3)(x+1)^3(x-2)(x-4)^2$.

Check with a grapher.

16) A model rocket is launched from the roof of a building with height h_0 . Its height above ground (in meters) t seconds later is given by $h = f(t) = -5t^2 + 40t + 20$.

a) The value of h_0 , the initial height of the rocket, is **20 meters**.

Figure 16a is not necessarily to scale.

b) The rocket will hit the ground, to two decimal places, in **8.47 seconds**.

Use the table to find the viewing window.

Figure 16b

c) The **exact** maximum height of the rocket is. **100 meters**.

X	Y ₁

8	20
9	-25
10	-80

← vertex

Table 16c

d) The rocket reach its maximum height in **4 seconds**.

e) The length of time the rocket will be 15 feet or higher, to two decimal places, is **8.12 seconds**.

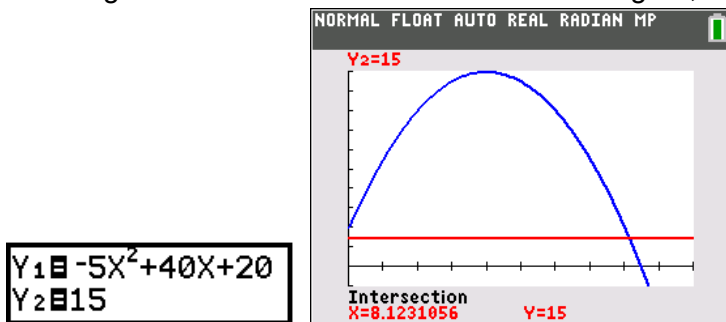

Figure 16e The formulas and graphs to solve $-5t^2 + 40t + 20 = 15$.

f) The domain (restricted according to the **context of the problem situation**) is $0 \leq t \leq 8.47$.

g) The range (restricted according to the **context of the problem situation**) is $0 \leq f(t) \leq 100$.

For more practice:

See the Flash Cards for Sections 2.4, 6.1, 6.2, 3.1, 3.2, and 11.1-11.3 as well as the Just for Practice sets.

Find these in your Brightspace course in the module **Flash Cards and Just for Practice Sets**.
